**Abbreviations:** ID: insufficient information

**Notes:**

1. Nutrients:

Oxidised N = NO<sub>2</sub> + NO<sub>3</sub>. Dissolved inorganic N (DIN) = Ammonium N + Oxidised N.

Except where specified for event conditions, nutrient guidelines do not apply during high flow events in fresh and estuarine waters. During periods of low flow and particularly in smaller creeks, build-up of organic matter derived from natural sources (e.g. leaf litter) can result in increased organic N levels (generally in the range of 400 to 800µg/L). This may lead to total N values exceeding the WQGs. Provided that levels of dissolved inorganic N remain low, then the elevated levels of organic N should not be seen as a breach of the WQGs, provided this is due to natural causes. See QWQG (section 5 and Appendix D) for more information on applying guidelines under high flow conditions.

2. Dissolved oxygen (DO): DO guidelines apply to daytime conditions. Lower values will occur at night in most waters. In estuaries, reductions should only be in the region of 10–15 per cent saturation below daytime values. In freshwaters, night-time reductions are more variable. Following significant rainfall events, reduced DO values may occur due to the influx of organic material. In estuaries post-event values as low as 40 per

cent saturation may occur naturally for short periods but values well below this would indicate some anthropogenic effect. In freshwaters, post-event DO reductions are again more variable. In general, DO values consistently less than 50 per cent are likely to impact on the ongoing ability of fish to persist in a water body while short term DO values less than 30 per cent saturation are toxic to some fish species. Very high DO (supersaturation) values can be toxic to some fish as they cause gas bubble disease. DO values for fresh waters should only be applied to flowing waters. Stagnant pools in intermittent streams naturally experience values of DO below 50 per cent saturation.

3. Temperature: Temperature varies both daily and seasonally, it is depth dependent and is also highly site specific. It is therefore not possible to provide simple generic WQGs for this indicator for fresh or estuarine waters. (In open coastal/marine waters a WQG based on GBRMPA WQGs is provided.) The recommended approach is that local WQGs be developed. Thus, WQGs for potentially impacted streams should be based on measurements from nearby streams that have similar morphology and which are thought not to be impacted by anthropogenic thermal influences. From an ecological effects perspective, the most important aspects of temperature are the daily maximum temperature and the daily variation in temperature. Therefore measurements of temperature should be designed to collect information on these indicators of temperature and, similarly, local WQGs should be expressed in terms of these indicators. There will be an annual cycle in the values of these indicators and therefore a full seasonal cycle of measurements is required to develop guideline values.

4. Fish: Fish metrics are a tool used to score or describe the health of an ecosystem based on the composition of the fish fauna. Scores may be compared against an expected or average condition derived from existing data sets or expert opinion. Tables 15-18 display fish metrics developed to score native fish species richness against an expected mean condition; non-native fish richness against an expected mean condition; native fish abundance against non-native fish abundance; an index of rarity (scoring for presence of rare species at a site); a recruitment index for both native and non-native fish species, and for upper catchment sites, a cold water species index. Some of the metrics rely on data from derived tables for electrofishing combined with fyke netting. These methods are important to implement in order to compare catch data to fish metrics. For a good score, native fish metrics should score high and non-native fish metrics score low (For further information refer to Hutchison, 2014).
